Abstract: Under continuous removal of water, the industrial protease Alcalase allows selective synthesis of α-carboxylic acid methyl, ethyl, benzyl, allyl, 2-(trimethylsilyl)ethyl, and tert-butyl esters of amino acids and peptides under mild conditions in very high yields. The purified yields range from 72% to 92%.

Key words: enzymes, amino acids, esterification, esters, protecting groups

There is a great demand for easily accessible amino acid building blocks for their use in peptide synthesis. For different applications, a large variety of side chain, α-amino and/or α-carboxylic acid protected amino acids is required. Orthogonality of the different protecting groups used is pivotal for conventional peptide synthesis protocols. Whereas the α-amino functions are most often protected as carbamates, the α-carboxylic acid functions are most often protected as esters. Esters can be synthesized by mineral acid catalysis using, for example, hydrochloric or sulfuric acid in the presence of the (unprotected) amino acid and the corresponding alcohol. However, this method is restricted to α-alkyl esters such as methyl, ethyl, or benzyl and for a subset of amino acids. More difficult to synthesize, but very commonly used as protecting groups in Fmoc- or Boc-based solid phase peptide synthesis, are the orthogonal esters such as the tert-butyl, allyl (All) or 2-(trimethylsilyl)ethyl (TMSE) esters. 2-(Trimethylsilyl)ethyl esters, cleavable with tetrabutylammonium fluoride,¹ and allyl esters, cleavable with palladium(0),² are orthogonal to other commonly used carboxylic acid protecting groups thus allowing selective deprotection and modification of certain carboxylic acids during peptide synthesis. Of special interest are α-carboxylic protected aspartic acid (Asp) or glutamic acid (Glu) building blocks, since these also contain a β- or γ-carboxylic acid moiety, respectively. These esters are used for (Fmoc- and Boc-based) on-resin synthesis of head-to-tail cyclic peptides,³ side-chain lactam peptides,⁴ and branched peptides.⁵

In chemoenzymatic peptide synthesis α-carboxylic acid esters are not only used for protection, but also, more importantly, for activation in the case of a kinetically controlled process. Most often, nonsterically hindered esters as methyl, ethyl, or benzyl esters are used as activated substrates.⁶

The chemical synthesis of amino acid esters in which the ester moiety is sterically demanding often requires harsh conditions, which is troublesome for sensitive substrates. For instance, tert-butyl esters are often synthesized using a strong mineral acid with isobutene under high pressure,⁷ which is laborious in laboratory practice. Furthermore, selective chemical α-carboxylic acid protection of aspartic acid and glutamic acid is difficult due to the similar reactivity of the side chain carboxylic acid functionalities. Although several one step methods have been described for (semi)selective side chain esterification,⁸ α-carboxylic acid protection of aspartic acid and glutamic acid usually needs multistep and/or low yielding protocols. For instance, the internal anhydride⁹ method and the chloroformate method¹⁰ both give approximately 3:2 mixtures of α-carboxy vs β/γ-carboxy esterification.

To overcome the selectivity issue and to avoid racemization, as is often encountered in chemical esterification, N-protected amino acids have been esterified using enzymes.¹¹ However, the water produced during the reaction and the water required for enzyme activity prohibits a favorable position for the esterification equilibrium resulting in low to moderate yields.¹² High yields were reported using esterases or lipases in dry organic solvents, but these enzymes are usually not selective for the α-carboxylic moiety. Proteases such as papain,¹³ chymotrypsin,¹⁴ and α-chymotrypsin¹⁵ are α-selective, but only demonstrated esterification with sterically undemanding alcohols such as methanol, ethanol, or benzyl alcohol. Esterification of amino acids to aliphatic esters with Alcalase has, to our knowledge, only been disclosed for Boc-Phe-OMe (65% in 48 h using subtilisin). Herein we demonstrate that the inexpensive industrial protease Alcalase¹⁶ (from Novozymes, 10 wt% Alcalase solution, 6.75 €/kg) can catalyze the esterification of a wide range of N-protected proteinogenic and nonproteinogenic amino acids in organic solvents at low water content with high α-carboxylic selectivity.

During an investigation of the Alcalase-catalyzed peptidic bond formation between Cbz-Phe-OMe and H-Leu-Or-Bu in tert-butyl alcohol at low water content,¹⁷ we discovered
a small percentage of byproduct (Scheme 1). HPLC/MS and NMR analysis proved this byproduct to be Cbz-Phe-Or-Bu.

To our knowledge, this transesterification to give a tert-butyl ester had not been previously reported. This is much to our surprise, because tert-butyl alcohol is generally the solvent of choice for protease-catalyzed peptide synthesis, and enzymes tend to have very good stability in this solvent. Further investigation of the tert-butyl ester formation from Cbz-Phe-OMe showed that, in the absence of the amino acid nucleophile H-Leu-Or-Bu, in neat tert-butyl alcohol the tert-butyl ester could be obtained in 75% yield. Upon addition of 4 Å molecular sieves Cbz-Phe-OMe was converted into Cbz-Phe-Or-Bu in 96% yield (50 °C, 48 h), indicating that the amounts of water and methanol were critical for the reaction outcome. Most strikingly, equally high yields could be obtained starting from the free carboxylic acid Cbz-Phe-OH (50 °C, 16 h, 96% yield) using 3 Å molecular sieves whereas in the absence of molecular sieves only low yields (48 h, 37% yield) of Cbz-Phe-Or-Bu were obtained. Apparently, continuous removal of water shifts the equilibrium towards product, with the enzyme remaining active. We decided to investigate the scope of the methodology using N-terminal protected amino acids, e.g., threonine, isoleucine, and valine were not efficiently accepted by Alcalase. The dipeptide Cbz-Phe-Leu-OH proved to be a good substrate for esterification reactions butyl ester had not been previously reported. This is much to our surprise, because tert-butyl alcohol is generally the solvent of choice for protease-catalyzed peptide synthesis, and enzymes tend to have very good stability in this solvent.

Further investigation of the tert-butyl ester formation from Cbz-Phe-OMe showed that, in the absence of the amino acid nucleophile H-Leu-Or-Bu, in neat tert-butyl alcohol the tert-butyl ester could be obtained in 75% yield. Upon addition of 4 Å molecular sieves Cbz-Phe-OMe was converted into Cbz-Phe-Or-Bu in 96% yield (50 °C, 48 h), indicating that the amounts of water and methanol were critical for the reaction outcome. Most strikingly, equally high yields could be obtained starting from the free carboxylic acid Cbz-Phe-OH (50 °C, 16 h, 96% yield) using 3 Å molecular sieves whereas in the absence of molecular sieves only low yields (48 h, 37% yield) of Cbz-Phe-Or-Bu were obtained. Apparently, continuous removal of water shifts the equilibrium towards product, with the enzyme remaining active. We decided to investigate the scope of the methodology using N-terminal protected phenylalanine as the model substrate (Scheme 2). Cross-linked enzyme aggregate (CLEA) was used since it could be easily dried and recovered after the reaction by filtration. Due to the well-known inactivation of Alcalase by methanol and polar aprotic solvents (such as DMSO and DMF), apolar co-solvents were used (i.e., n-heptane, toluene, or MTBE) in the esterification reactions. All reported esterification reactions with primary alcohols were performed using a mixture of the appropriate alcohol with methyl tert-butyl ether (1:14, v/v, respectively).

As is shown in Table 1, Cbz-protected phenylalanine was smoothly converted into a variety of esters 1a–6e in very high yields. The choice of N-terminal protection (6a–e) did not influence the esterification reaction. As is known from the literature, Alcalase accepts a wide variety of proteinogenic (7a–e) and nonproteinogenic (7f) amino acids, which was also demonstrated for tert-butyl ester synthesis (Table 2). Only amino acids with a tertiary β-carbon, e.g., threonine, isoleucine, and valine were not efficiently accepted by Alcalase. The dipeptide Cbz-Phe-Leu-OH proved to be a good substrate for esterification reactions giving 8–10. Under the dry conditions used, neither hydrolysis nor alcoholysis of the peptidic bond was observed.

Since the use of molecular sieves is inconvenient on large scale, azetotropic water removal was investigated. Gratifyingly, the tert-butyl esters were formed in high yields (>95%) when tert-butyl alcohol, which forms an azetrope with water, was continuously evaporated and dry tert-butyl alcohol was simultaneously added to keep the reaction volume constant. Alcohols, which do not form an azetrope with water, was continuously evaporated and dry tert-butyl alcohol was simultaneously added to keep the reaction volume constant. Alcohols, which do not form an azetrope with water, such as allylic alcohol and 2-(trimethylsilyl)ethanol, could be combined with the azetropic solvent toluene (1:14, v/v, respectively), under reduced pressure, to obtain ester yields of up to 98%. The CLEA-Alcalase could be recycled with minimal activity loss; after filtration, new starting materials were added and only 1% activity loss occurred after five esterification cycles.
high yields and with complete selectivity into their corresponding monoesters aspartic acid and glutamic acid derivatives were converted into various N-protecting groups (Scheme 3). Gratifyingly, all nine to aspartic acid and glutamic acid derivatives with aspartic acid functionality in the side chain, e.g. aspartic acid and glutamic acid, were esterified with complete selectivity towards a variety of esters by Alcalase in very high to excellent yields. Even esters that are difficult to synthesize chemically, e.g. tert-butyl esters, were obtained in high yields. Furthermore, amino acids with an additional carboxylic acid moiety. The processes appeared amenable to scale-up since the water could also efficiently be removed by azeotropic distillation and the CLEA-Alcalase could be recycled with minimal loss of activity.

Unless stated otherwise, chemicals were obtained from commercial sources and used without further purification. Before use CLEA-Alcalase was dried as follows: CLEA-Alcalase (3 g, Codexis, 650 AGEU/g, 3.5 wt% H2O), was suspended in t-BuOH (100 mL) and crushed with a spatula. After filtration, the enzyme was resuspended in MTBE (50 mL) followed by filtration. 1H and 13C NMR spectra were recorded on a Bruker Avance 300 MHz NMR spectrometer; chemical shifts are given relative to TMS. TLC was performed on pre-coated silica gel 60 F254 plates (Merck); spots were visualized using UV light, ninhydrin, or permanganate soln. 3 Å molecular sieves were dried under reduced pressure at 200 °C and t-BuOH was stored on these activated molecular sieves. t-BuOH was pre-heated to liquid (45 °C) before use. Column chromatography was carried out using silica gel, Merck grade 9385 60 Å. Analytical HPLC was performed on an HP1090 Liquid Chromatograph, using a reversed-phase column (Inertsil ODS-3, C18, 5 μm particle size, 150 × 4.6 mm internal diameter) at 40 °C. UV detection was performed at 220 nm using a UV-Vis 204 Linear spectrophotometer (Varian). The gradient program was: 0–25 min linear gradient from 5% to 98% eluent B and from 25.1–30 min 5% eluent B (eluents A: 0.5 mL/L MeOH in H2O; eluent B: 0.5 mL/L MeOH in MeCN). The flow was 1 mL/min from 0–25.1 min and 2 mL/min from 25.2–29.8 min, then back to 1 mL/min until stop at 30 min. Injection volumes were 20 μL.

The flow-injection analysis (FIA) experiments to determine the exact mass were performed on an Agilent 1100 LC-MS system (Agilent, Waldbronn, Germany), which consists of a binary pump, degasser, autosampler, column oven, diode-array detector, and a TOF-MS. The ESI-MS was run in positive mode, with the following conditions: m/z 50–3200, 175 V fragmentor, 0.94 cycl/sec, 350 °C drying gas temperature, 10 L N2/min drying gas, 45 psig nebulizer pressure and 4 kV capillary voltage. The exact mass was determined using an internal reference to recalibrate the m/z axis for each measurement. The samples were directly introduced into the ESI by crushed with a spatula. After filtration, the enzyme was resuspended in MTBE (50 mL) followed by filtration. 1H and 13C NMR spectra were recorded on a Bruker Avance 300 MHz NMR spectrometer; chemical shifts are given relative to TMS. To investigate the α-carboxylic acid selectivity of Alcalase we decided to apply the conditions as for phenylalanine to aspartic acid and glutamic acid derivatives with various N-protecting groups (Scheme 3). Gratifyingly, all aspartic acid and glutamic acid derivatives were converted into their corresponding monoesters 11a–16b in very high yields and with complete α-selectivity (Table 3).

### Scheme 3

In conclusion, we have developed a general versatile method for enzymatic α-carboxylic acid selective esterification of N-protected amino acids and peptides towards a variety of esters by Alcalase in very high to excellent yields. Even esters that are difficult to synthesize chemically, e.g. tert-butyl esters, were obtained in high yields. Furthermore, amino acids with an additional carboxylic acid functionality in the side chain, e.g. aspartic acid and glutamic acid, were esterified with complete selectivity for the α-carboxylic moiety. The processes appeared amenable to scale-up since the water could also efficiently be removed by azeotropic distillation and the CLEA-Alcalase could be recycled with minimal loss of activity.
Enzymatic Esterification with tert-Butyl Alcohol; General Procedure

CLEA-Alcalase (300 mg) was added to N-protected amino acid (0.167 mmol) dissolved in MTBE (2.8 mL) and the appropriate alcohol (200 μL). The mixture was shaken at 50 °C for 150 rpm for 16 h. After filtration, the enzyme was washed three times by resuspension in EtOAc (20 mL) followed by filtration. The combined organic layers were concentrated in vacuo and the resulting oil redissolved in toluene (2 × 20 mL) and CHCl3 (2 × 20 mL). For Chz-Ser-Or-Bu (7e) additional column chromatography (n-heptane-EtOAc, 1:1) was required.

Enzymatic α-Selective Esterification of N-Protected Aspartic Acid and Glutamic Acid; General Procedure

CLEA-Alcalase (3 g) was added to N-protected amino acid (0.5 g), MTBE (28.0 mL), the appropriate alcohol (2.0 mL), and 3 A molecular sieves (2.0 g). The mixture was shaken at 50 °C with 150 rpm for 16 h. After filtration, the enzyme was washed three times by resuspension in aq HCl (pH 1, 50 mL) and three times by resuspension in EtOAc (50 mL) followed by filtration. The combined EtOAc and HCl phases were separated and the organic phase was washed with aq HCl (pH 1, 100 mL), dried (Na2SO4), and concentrated in vacuo. The resulting oil was redissolved in CHCl3–MeOH–AcOH (89.9:10.0:1.20) and mixed with silica gel filtration. The mixture was concentrated in vacuo and co-evaporated with toluene (2 × 50 mL) and CHCl3 (concentrated to a concentration of 25 μL).

13C NMR (75 MHz, CDCl3): δ = 28.4, 34.7, 50.1, 66.0, 80.7, 119.0, 131.7, 155.9, 171.1, 175.9.

MS [FIA-ESI(+)-TOF]: m/z [M + Na]+ calcd for C14H24N2NaO5: 296.1134; found: 296.1117.

N-(Benzoylcarbonyl)glutamic Acid α-Allyl Ester (13a)

1H NMR (300 MHz, CDCl3): δ = 1.42 (s, 9 H, CCH3), 1.94–2.03 (m, 1 H, CH2), 2.15–2.21 (m, 1 H, CH2), 2.41–2.47 (m, 2 H, CH2), 4.34–4.36 (m, 1 H, CH), 4.61 (d, J = 5.7 Hz, 2 H, COOCH2), 5.26–5.35 (m, 3 H, NH, =CH2), 5.83–5.94 (m, 1 H, CH=), 9.44 (s, 1 H, COOH).

13C NMR (75 MHz, CDCl3): δ = 27.1, 28.2, 30.1, 52.9, 66.0, 80.1, 118.9, 131.5, 155.5, 172.0, 177.5.

MS [FIA-ESI(+)-TOF]: m/z [M + Na]+ calcd for C17H24N2NaO5: 310.1261; found: 310.1266.
