Dedicated to Professor George A. Olah on the occasion of his 75th birthday.

Abstract: The sterically congested Lewis acid 1 was used as a catalyst in the Prins reaction of various styrenes and formaldehyde. 4-Aryl-1,3-dioxanes 5 were selectively formed as the exclusive products of the reaction with styrenes 4a–l and vinylthiophenes 4j–k. The reaction proceeded in most cases with good to excellent yields (55–99%). Styrenes which carried a strongly electron-withdrawing group (CN, CO₂Me) did not react. The reaction with 2-alkylstyrenes 6 was successful for the methyl substituted substrate 6a and yielded (88%) trans-5-methyl-4-phenyl-1,3-dioxane (7a) preferentially (dr = 75:25). For steric reasons, other β-alkylstyrenes 6b–d did not react. The remarkable stereodiscrimination attained by catalyst 1 was employed in the regioselective transformation of 4-propenylstyrene (10) to dioxane 11 (83% yield).

Keywords: carbocations, catalysis, chemoselectivity, electrophilic additions, Lewis acids

The Prins reaction of alkenes A and formaldehyde can proceed to a variety of products depending on the reaction conditions (Scheme 1). Major products commonly observed include 1,3-dioxanes B, 1,3-diols C and allylic alcohols D. Homoallylic alcohols are also accessible from the same starting materials but they are often formed by a mechanistically different pathway (carbonyl-ene reaction). Additional side reactions may further complicate the outcome of the reaction. In particular, a polymerization of the olefin which is induced by Lewis or Brønsted acids can severely interfere with the desired C–C-bond formation.

We became interested in the Prins reaction because of its high synthetic versatility. A double bond functionalization can be nicely combined with a C–C-bond formation in a single step provided there is a significant type selectivity for either product B, C or D. At least one stereogenic center is formed in the course of the reaction to B or C. Our major focus was to find suitable conditions for the conversion of styrenes to the corresponding 1,3-dioxanes. Ideally, we looked for a catalytic reaction system with the Lewis acid being used in substoichiometric amounts. Preliminary studies with BF₃ as the Lewis acidic catalyst and styrene as the alkene under various conditions revealed that the chemoselectivity of the BF₃-catalyzed reaction was not sufficient. Yields remained under 50% and many side reactions were observed. In search of less active, but more selective catalysts, we considered the use of sterically congested alkoxy- and aryloxyboron halides. Recent synthetic studies by Meller et al. had provided several boron compounds, e.g. 1–3 (Figure 1), which appeared interesting Lewis acids for our purpose. Whereas diaryloxyboron fluoride 2 and dialkoxyboron fluoride 3 turned out to be not sufficiently reactive the aryloxyboron difluoride 1 was found well suited to catalyze the Prins reaction of styrenes. Details of the reactions conducted by us are reported in this account.

Catalyst 1 is a liquid which can be purified by distillation in vacuo. It can be stored at −30 °C for several weeks without loosing its catalytic activity. Optimized reaction conditions which we used in all Prins reaction experiments included the use of paraformaldehyde [(CH₂O)n] as the formaldehyde source and 1,4-dioxane as the solvent. A catalyst loading of 10 mol% turned out to be ideal. The use of a lower catalyst/substrate ratio (5 mol%) led to longer reaction times or to incomplete conversion. The selectivity (type selectivity and chemoselectivity) of the catalyzed reaction is remarkable. In all instances, the styrenes 4 were converted exclusively to the 1,3-dioxanes.
5 (Scheme 2). Other side products were not observed. The reaction temperature had to be adjusted depending on the substituent on the styrenes (Table 1). The parent compound 4a reacted at 80 °C and gave the corresponding dioxane 5a in 95% yield. Electron-donating substituents with a negative Hammett constant \( \sigma_p \) facilitated reactions at lower temperature. The reactive vinylthiophenes 4j and 4k also reacted under milder conditions (75 °C) and yielded the hitherto unknown 1,3-dioxanes 5j and 5k. Styrenes substituted with an electron-withdrawing group reacted less readily and required higher reaction temperatures. Reactions which were conducted at 100 °C with the para-substituted styrenes 4d and 4i \( \sigma_p (\text{Cl}) = 0.22, \sigma_p (\text{OAc}) = 0.18 \) serve as examples.

Scheme 2

Varying the location of the chlorine substituents in the chloroarylstyrenes 4d-f showed that an ortho-substituent does not significantly alter the outcome of the reaction. Both 2-(4f) and 4-chlorostyrene (4d) reacted smoothly to give the corresponding products in good yields. The lower reactivity of the meta-compound 4e is attributed to the higher electron acceptor power of chlorine in meta-position \( \sigma_p (\text{Cl}) = 0.37 \). Indeed, it appears as if the reactivity of the electrophile, which is presumably a formaldehyde-Lewis acid \( \text{H}_2\text{CO} \cdot 1 \) complex, is sufficient to attack styrenes, the substituents of which exhibit a Hammett constant \( \sigma_p \leq 0.40 \). More deactivating substituents prohibit the reaction completely. Accordingly, 4-cyano \( \sigma_p (\text{CN}) = 0.71 \) and 4-methoxycarbonylstyrene \( \sigma_p (\text{CO}_2\text{Me}) = 0.44 \) did not react. It is unlikely that the failure of these reactions is due to a deactivation of the Lewis acid by carbonyl complexation as other esters 4i and even amides 4g, 4h did react. Along these lines, the unsuccessful attempt to convert 4-vinylpyridine to its 1,3-dioxane derivative is easy to understand.

1-Phenylprop-1-ene (6a) underwent a stereoselective Prins reaction under the typical reaction conditions. The trans-1,3-dioxane 7a was formed in excess relative to the cis-isomer 8a (dr = 75:25) (Scheme 3). The reaction proceeded not stereospecifically but in a stereoconvergent fashion, i.e. the diastereomeric ratio was not dependent on the configuration of the styrene. Experiments conducted with pure trans-6a and with a cis/trans-mixture resulted in identical yields and diastereoselectivities. The diastereoselectivity is higher than previously observed for the analogous Prins reaction promoted by Bronsted acids. Depending on the acid and the reaction conditions diastereomeric ratios of dr = 64:36 to 37:63 have been reported.

\( \sigma_p (\text{Me}) = –0.14, \sigma_p (\text{OMe}) = –0.28, \sigma_p (\text{p} \text{Cl}) = 0.22, \sigma_p (\text{OAc}) = 0.18 \)

The diastereomerically pure 1,3-dioxane 7a was subjected to the typical Prins reaction conditions. An equilibration to compound 8a was not observed. We therefore conclude that the products are formed in a kinetically controlled reaction, which proceeds irreversibly to the two diastereoisomers. A possible explanation for the preference in favor of 7a is based on the generally accepted mechanism.
of the Prins reaction. Accordingly, the styrene is attacked by an activated formaldehyde molecule (complex H₂CO·1) in the first reaction step. As a cyclization to a four-membered oxetane is disfavored, a second formaldehyde molecule is incorporated leading to a 1,3-dioxane. In the case of compound 6a, a potential cyclization precursor is the chiral carbenium ion 9a. The two faces of the carbenium ion are diastereotopic due to the adjacent stereogenic center. A differentiation results from the size difference of the hydrogen atom and the methyl group. The hydrogen atom adopts the pseudoaxial position in the transition state of the cyclization as depicted in Figure 2. The hypothesis of a carbenium ion intermediate is in line with the observed stereoconvergency of the reaction.

Due to the steric bulk of the Lewis acid 1, a potential electrophilic complex H₂CO·1 is sensitive towards the substitution pattern in β-substituted styrenes. Whereas 1-phenylprop-1-ene (6a) showed reasonable reactivity (vide supra) other styrenes 6b–d (Figure 2) did not react at all. In this respect, the Lewis acid allows for a differentiation between a methyl and an ethyl substituted styrene. Since compound 6a reacted already significantly slower than the unsubstituted parent styrene (4a) we attempted a differentiation in a bifunctional substrate. To this end, compound 10 was prepared as a mixture of diastereoisomers (cis/trans = 36:64). Upon subjecting this bifunctional substrate to the catalytic reaction conditions (Scheme 4) at 80 °C dioxane 11 was the exclusive reaction product (diastereomeric mixture, cis/trans = 36:64). The result supports the high selectivity, which can be achieved with Lewis acid 1.

All reactions involving water-sensitive chemicals were carried out in flame-dried glassware with magnetic stirring under Ar. All experiments were performed in Fluka p.a. solvents. The styrenes were either commercially available or they were prepared according to known protocols: acetamidostryrenes 4g/h, vinylthiophenenes 4j/k. Common solvents for chromatography [Et₂O, pentane (P), EtOAc] were distilled prior to use. TLC was performed on aluminum sheets (0.2 mm silica gel 60 F₂₅₄) with detection by UV (254 nm) or by coloration with ceric ammonium molybdate (CAM). Flash chromatography was performed on silica gel 60 (Merck, 230–400 mesh) (ca. 50 g for 1 g of material to be separated) with the indicated eluent. Melting points (uncorrected): Reichert hot bench. IR: Perkin Elmer 1600 FT-IR. MS: Varian CH7 (EI). HRMS: Finnigan MAT 95S or MAT 8200. GC-MS: Agilent 6890 (GC system). Agilent 5973 (Mass selective detector). 1H and 13C NMR: Bruker AMX-250 and AV-360. 1H and 13C NMR spectra were recorded at 303 K. Chemical shifts are reported relative to tetramethylsilane as an internal reference. The multiplicities of the 13C NMR signal were determined by DEPT experiments.

**Figure 2** Putative intermediate 9a en route to the formation of compound 7a and other β-alkylstyrenes 6b–d

Due to the steric bulk of the Lewis acid 1, a potential electrophilic complex H₂CO·1 is sensitive towards the substitution pattern in β-substituted styrenes. Whereas 1-phenylprop-1-ene (6a) showed reasonable reactivity (vide supra) other styrenes 6b–d (Figure 2) did not react at all. In this respect, the Lewis acid allows for a differentiation between a methyl and an ethyl substituted styrene. Since compound 6a reacted already significantly slower than the unsubstituted parent styrene (4a) we attempted a differentiation in a bifunctional substrate. To this end, compound 10 was prepared as a mixture of diastereoisomers (cis/trans = 36:64). Upon subjecting this bifunctional substrate to the catalytic reaction conditions (Scheme 4) at 80 °C dioxane 11 was the exclusive reaction product (diastereomeric mixture, cis/trans = 36:64). The result supports the high selectivity, which can be achieved with Lewis acid 1.

**Scheme 4**

In summary, the boron compound 1 was found to be an effective and selective catalyst for the Prins reaction of several styrenes. Due to its steric bulk, the catalyst allows for a decent diastereoselectivity and a remarkable site-selectivity in this reaction. Possible applications of these selectivities are currently studied more closely. In addition, chiral analogues of compound 1 are being prepared to evaluate enantioselective variants of the Prins reaction.
